- Fast-waves and large-scale disturbances (e.g. EIT waves) seen to travel large distances in the corona, often across different magnetic field structures/environments.
- Through interaction with local environment, these waves can trigger energy release through *magnetic reconnection*.
- Significant energy release often only achieved for collisional models via large current densities & small lengthscales *MHD model self-consistent*?
- <u>Potential solution</u>: include additional terms in generalised Ohm's Law.
- Focus on Hall term study *wider range of scales* than MHD, with *minimal additional complexity*.

Q: How does the Hall term affect MHD waves and (wave-triggered) reconnection?

Introduction O Waves & X-points (MHD) •000 Uniform Hall MHD 00 Waves & X-points (Hall MHD 000 Conclusions O References

Fast-wave/X-point interaction in MHD

- McLaughlin et al. (2009) studied interaction of initial nonlinear fast-wave with an X-point.
- Benchmark using Lare2d code (Arber et al., 2001)
- Equilibrium: **B** $= B_0[-x, y, 0], β = 0,$ *T*= 0, (x, y) ∈ [-20, 20],5120 × 5120 grid
- $\diamond \quad \frac{\text{Initial Perturbation}}{\xi_{\perp}(0) = 2C \sin (\pi [r 4.5])}$
- Nonlinear amplitude (C = 0.5) allows pulse to reach the null.

♦ t = 0.8: replace outward travelling pulse with initial config. & damping layer

Current oscillations - MHD

Like McLaughlin et al. (2009), find distinctive oscillations of current at the null, which decrease with time:

What drives later oscillatory behaviour?

Oscillatory behaviour - MHD

- Whether −∇p or J × B dominates in one quadrant depends on initial config.
- Each restores overshoot brought on by other.
- Successive responses progressively smaller.
- Could the inclusion of the Hall term affect this cycle?

		Hall MHD	- recap!		

$$\mathbf{E} + \mathbf{u} \times \mathbf{B} = \eta \mathbf{J} + \frac{1}{ne} \mathbf{J} \times \mathbf{B}$$

- Hall MHD appropriate for high frequency perturbations ($\omega \sim \Omega_i$) and small lengthscales ($L \sim \delta_i$).
- Two distinct wave-branches emerge as $k\delta_i$ increases:
 - whistler wave (super-Alfvénic) dispersive
 - ion-cyclotron wave (sub-Alfvénic, ultimately constant frequency)
- Branches introduce circular polarisation and dispersive effects when applied to waves/pulses

[Details given in Section 2 of Threlfall et al. (2011, A&A 525 A155)]

• Initially shear waves quickly couple to fast waves (and vice-versa) and rapidly broaden - how quickly determined by δ_i .

Uniform Hall MHD

Waves & X-points (Hall MHI 000 Conclusions O References

Hall MHD - single pulse, uniform field

- Example: initially shear pulse, kδ_i ≪ 1.
- Shear Alfvén wave no longer plane polarised for finite δ_i .
- Implications for wave annulus and shock formation in X-point field.
- How are X-point collapse (and resulting reconnection) affected?

▲ロト ▲帰 ト ▲ヨト ▲ヨト - ヨ - の々ぐ

Fast-wave/X-point interaction - Hall MHD

- $k\delta_i \ll 1$ limit yields near-identical behaviour to MHD in X-point simulations.
- kδ_i ≫ 1 limit difficult to simulate.
- kδ_i ~ 1 simulations show significant differences in initial wave behaviour affecting X-point collapse.
- NB. "Diffraction-like pattern" caused by Hall effects and initial conditions (**not** interaction with boundary)!

Reconnection in Hall MHD

Two distinct categories of reconnection:

1. Initial X-point collapse:

- Highly dependent on δ_i .
- Whistler waves destabilise X-point earlier.
- Additional null pairs generated.
- Wide range of currents (inc. planar, J_x, J_y) at each null.

2. Oscillatory reconnection:

- Frequency appears independent of δ_i (for values tested).
- Cycle still driven by gas and magnetic pressures (as with MHD).

- Wave-triggered X-point collapse relaxes via oscillatory reconnection.
- Relaxation caused by competition of magnetic and gas pressure forces, restoring successive overshoots brought about by the other.
- In Hall MHD, whistlers and circular polarisation significantly modify initial wave and resulting X-point collapse for large values of δ_i .
- Whistlers cause rapid oscillations of field near original null, generating multiple additional null pairs.
- Arrival of main body of pulse causes additional nulls to recombine system then relaxes through oscillatory relaxation, with identical frequency to MHD case.
- Presence of additional nulls and planar currents prevents definitive conclusions regarding rate of reconnection.
