

Astrometry of H₂O maser sources in nearby star-forming regions with VERA

VERA array configuration

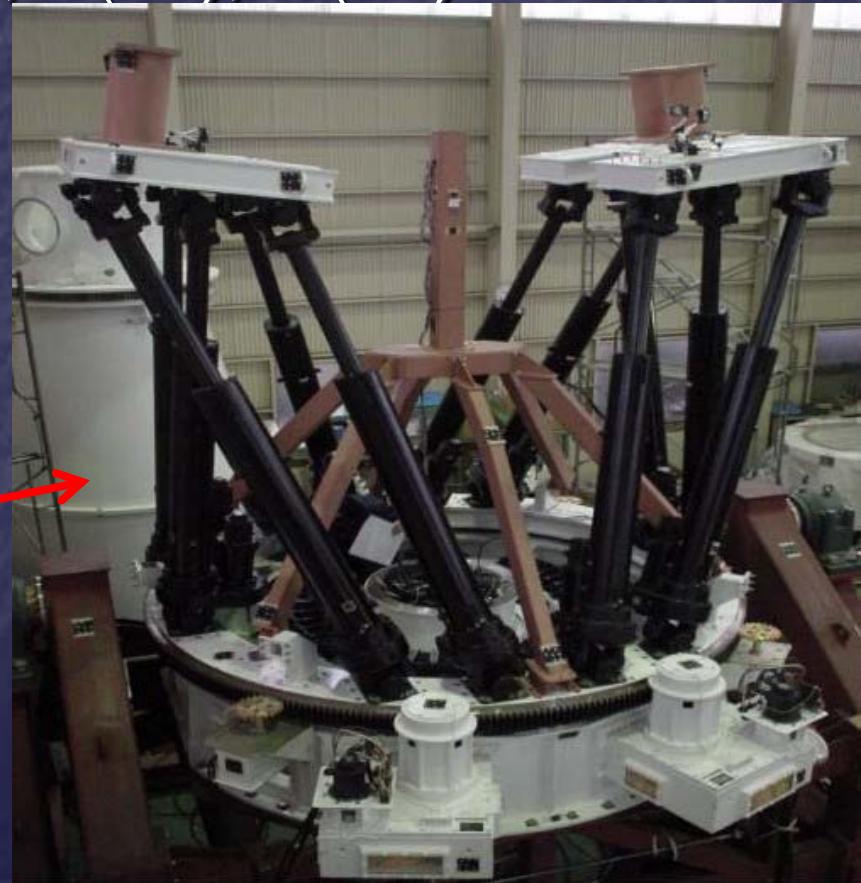

Tomoya HIROTA

(Mizusawa-VLBI Observatory, NAOJ)

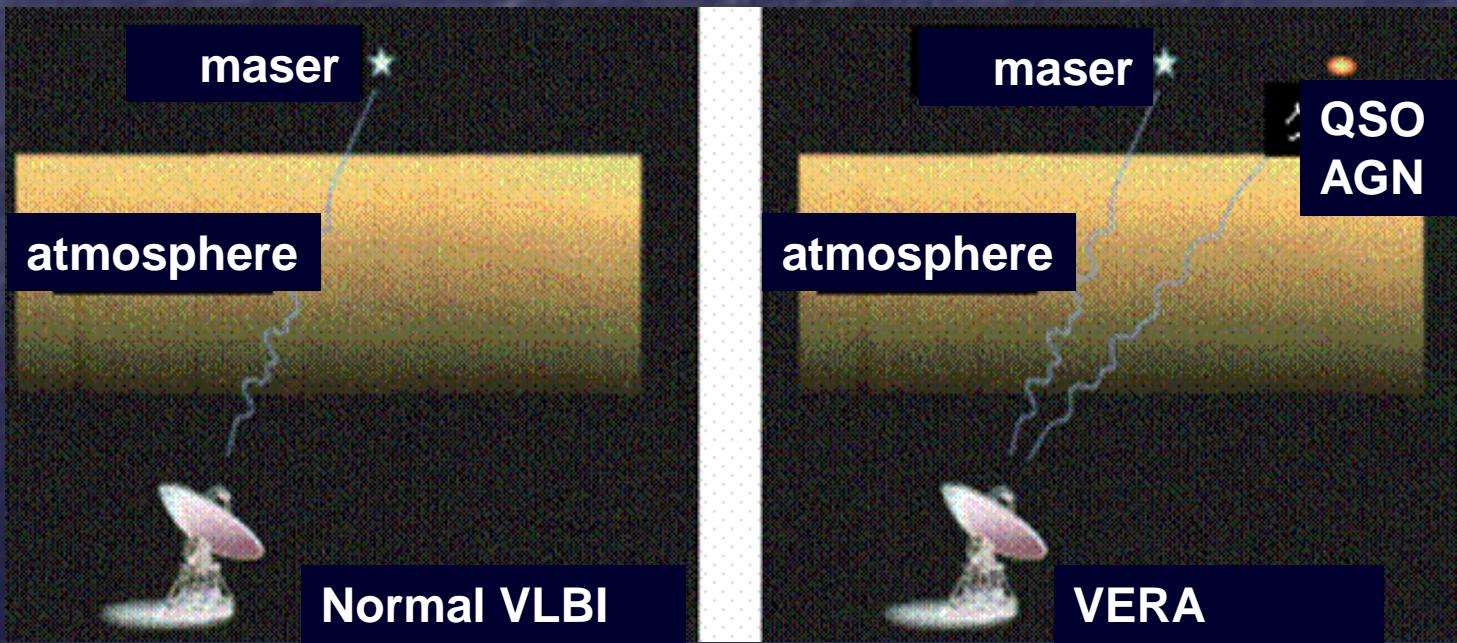

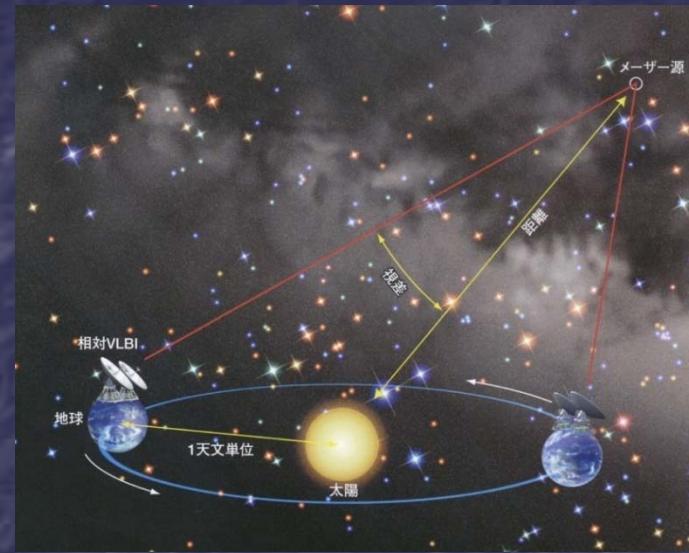

VERA: VLBI Exploration of Radio Astrometry

- Antenna diameter: 20m
- Frequency: S(2), C(6.7), X(8), K(22), Q(43)
- Baseline: 1000-2300 km
- Dual-beam system (K, Q)

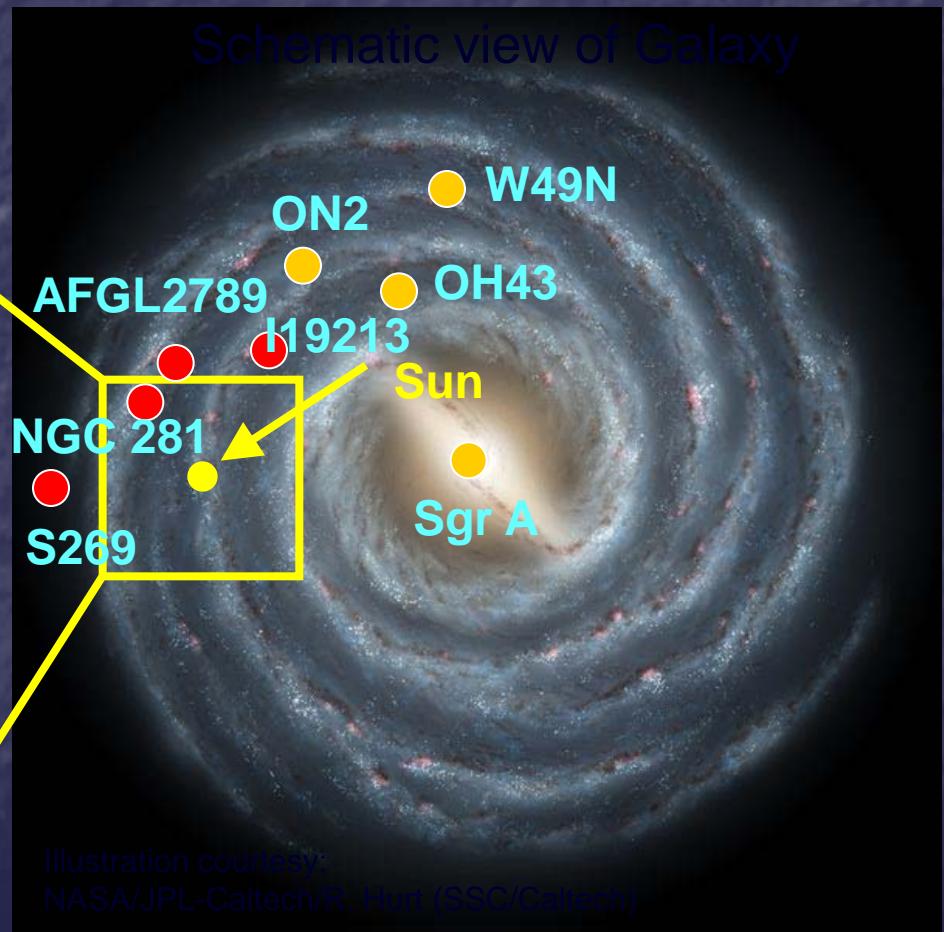

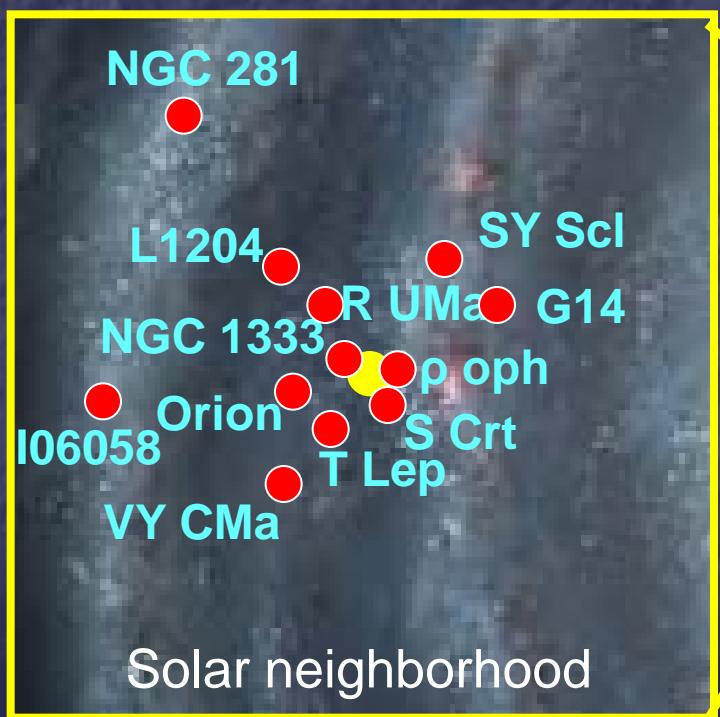

VERA

- Phase-referencing technique
 - Observation of target (maser) and reference sources simultaneously
 - Annual parallax measurements

Aim of VERA

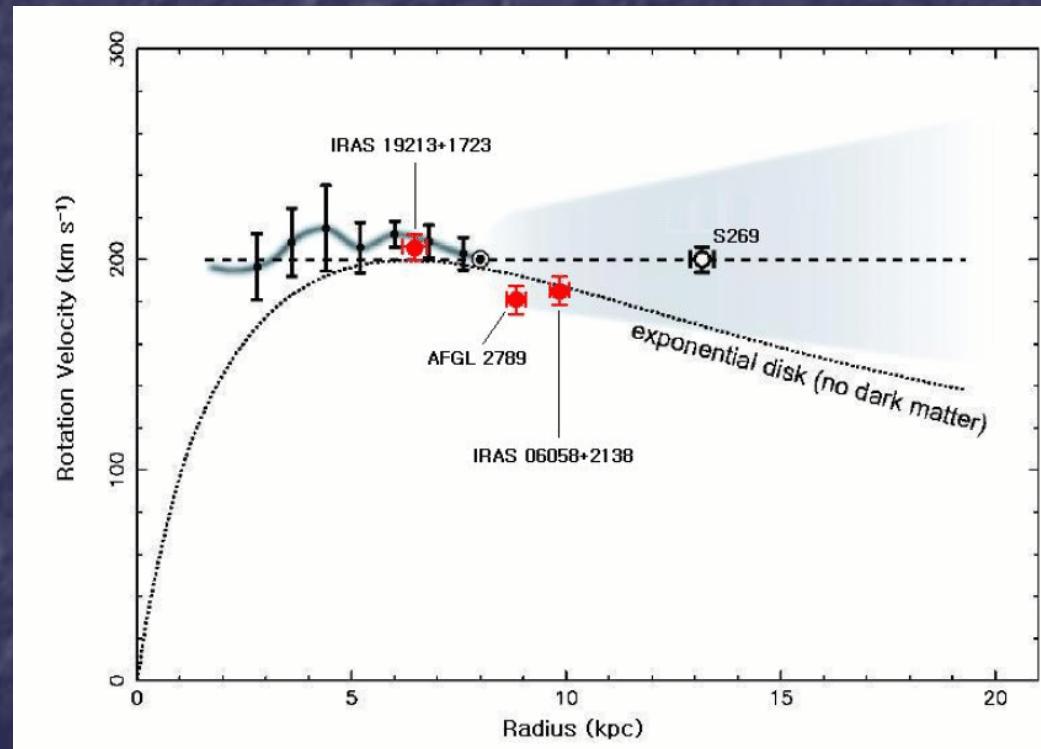

- Distance/proper motion measurements for masers
 - Reveal 3-D structure of our Galaxy

● Parallax + proper motion ● Proper motion

Rotation curve

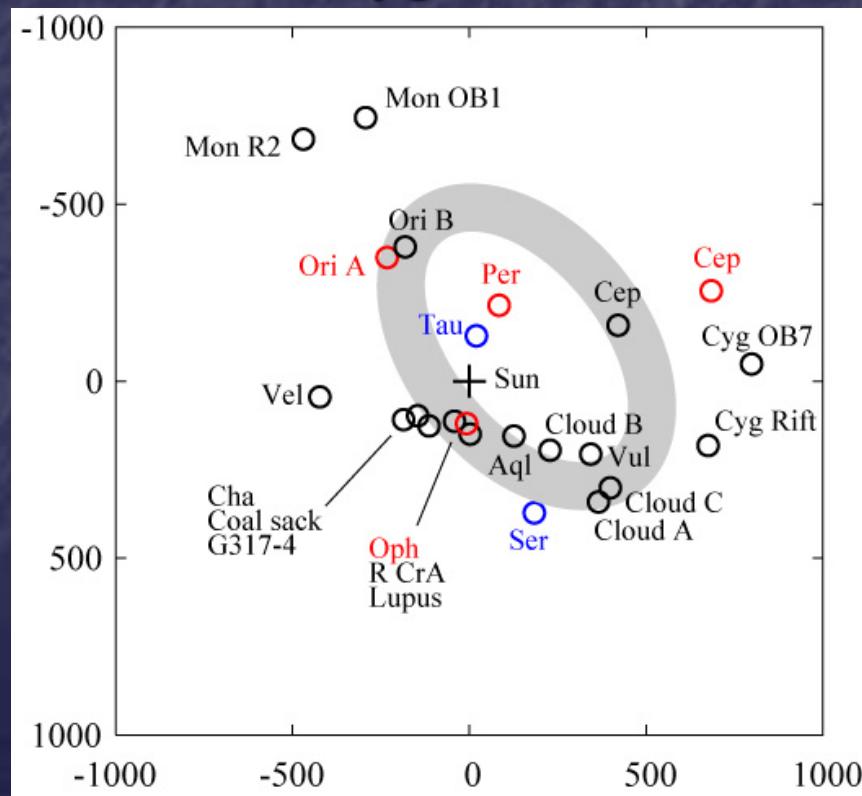

- Honma et al. (2007) and Oh et al. (2009)
 - S269
 - IRAS19213+1723
 - AFGL2789
 - IRAS06058+2138
 - D= 2-5 kpc
- Consistent with flat rotation curve, but a “dip” in Perseus arm

Nearby SFRs project

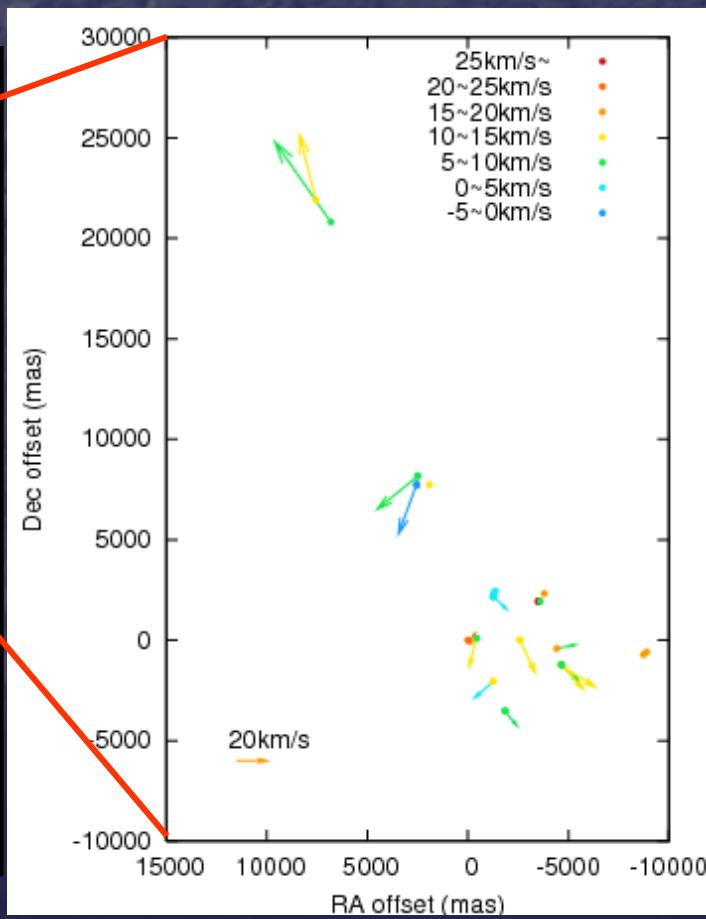

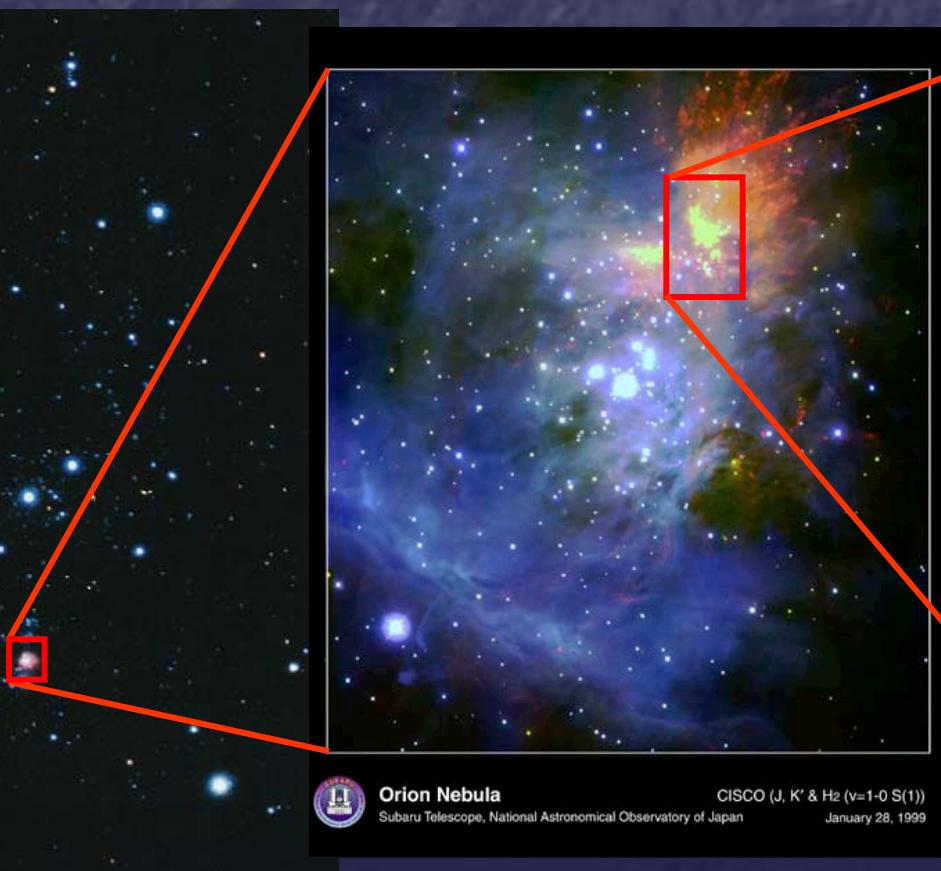

- Astrometry of H₂O masers in nearby SFRs (<1 kpc)
 - Orion (Orion A), Cepheus, Perseus
 - Taurus, Ophiuchus, Serpens, Monoceros, Cygnus ...
- Aim of this project
 - Fundamental database
 - Refine physical processes in star/planet-formation
 - Reveal 3-D structure of Gould belt and local bubble

Distribution of nearby SFRs
(based on Dame et al. 1987 and Ward-Thompson et al. 2007)

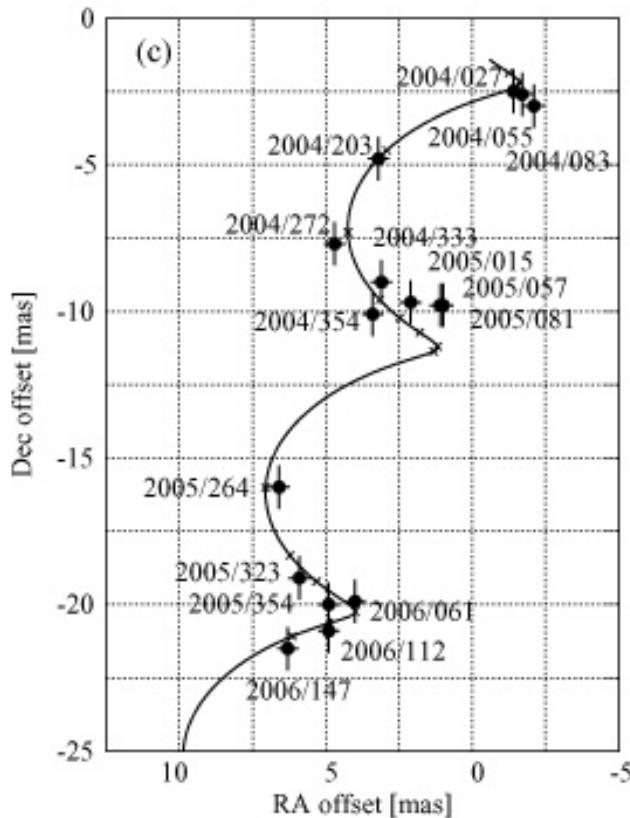

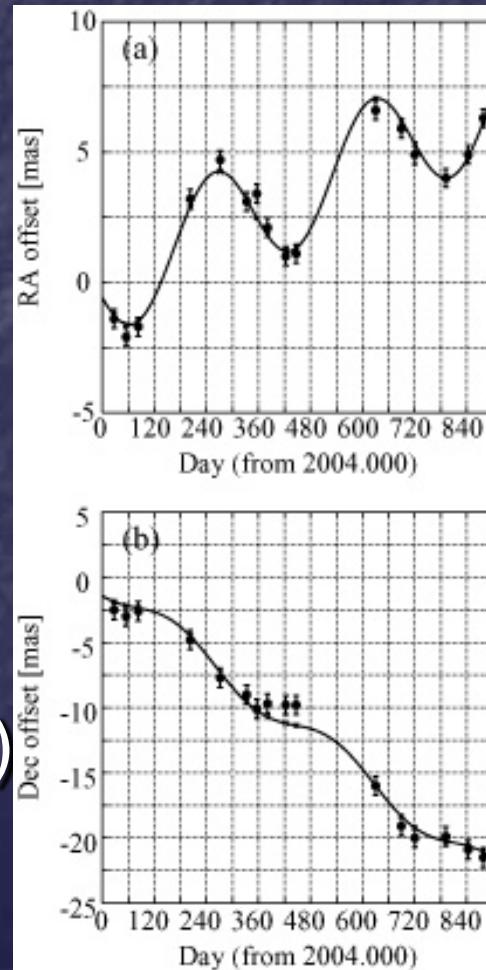

Orion KL

- Famous H₂O maser source (e.g. Genzel et al. 1981)

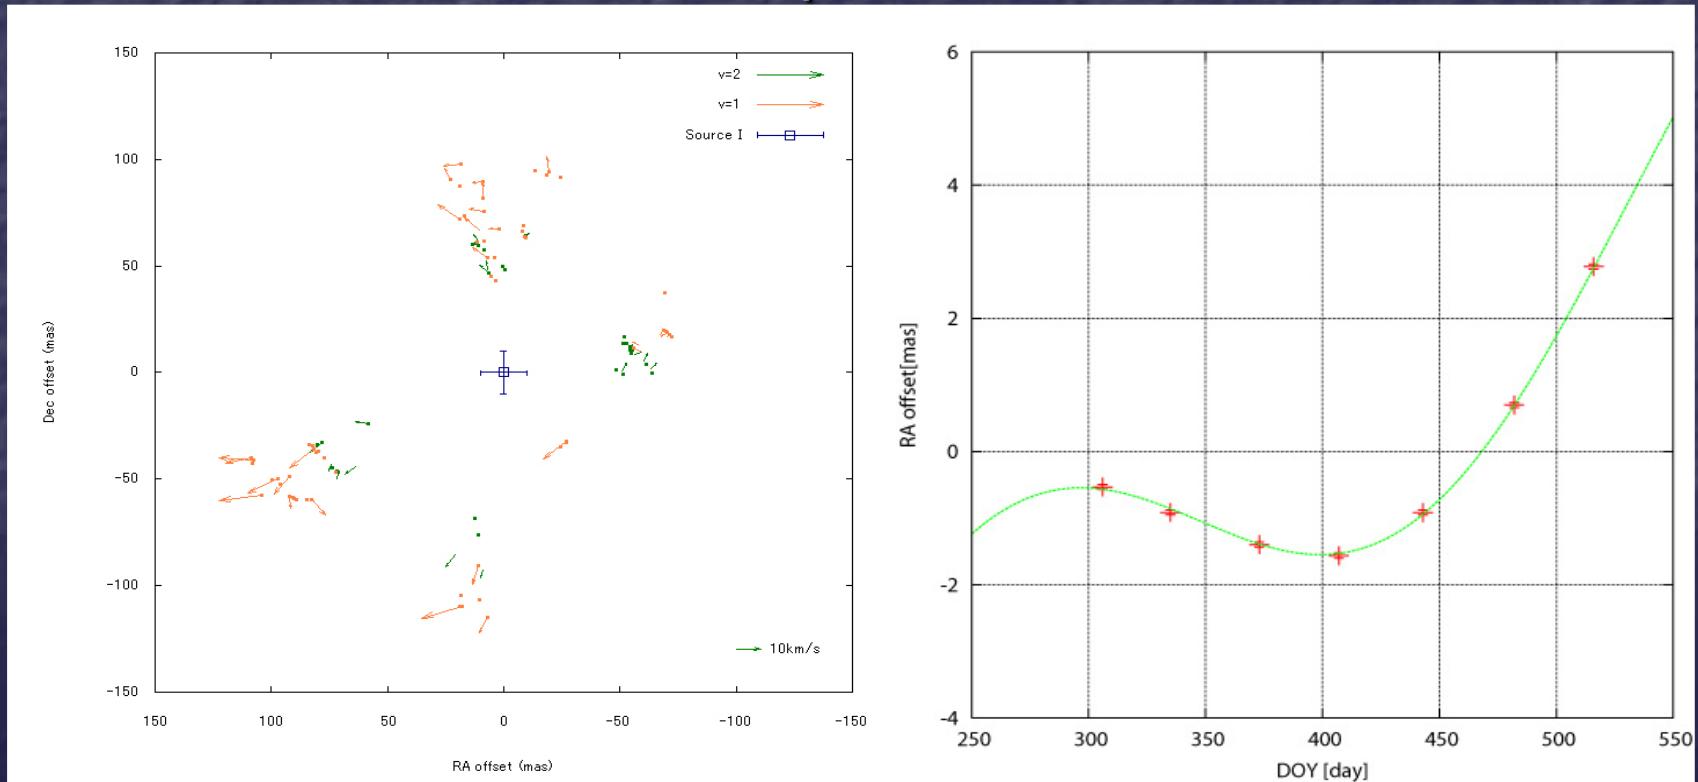

Distance to Orion KL

- The first result by Hirota et al. (2007)
 - Single H₂O maser
 - 2.29 ± 0.10 mas = 437 ± 19 pc
- Smaller than well known value = 480 pc
(Genzel et al. 1981)

Distance to Orion KL

- Refined by Kim et al. (2008)
 - Single SiO maser
 - $2.39 \pm 0.03 \text{ mas} = 418 \pm 6 \text{ pc}$

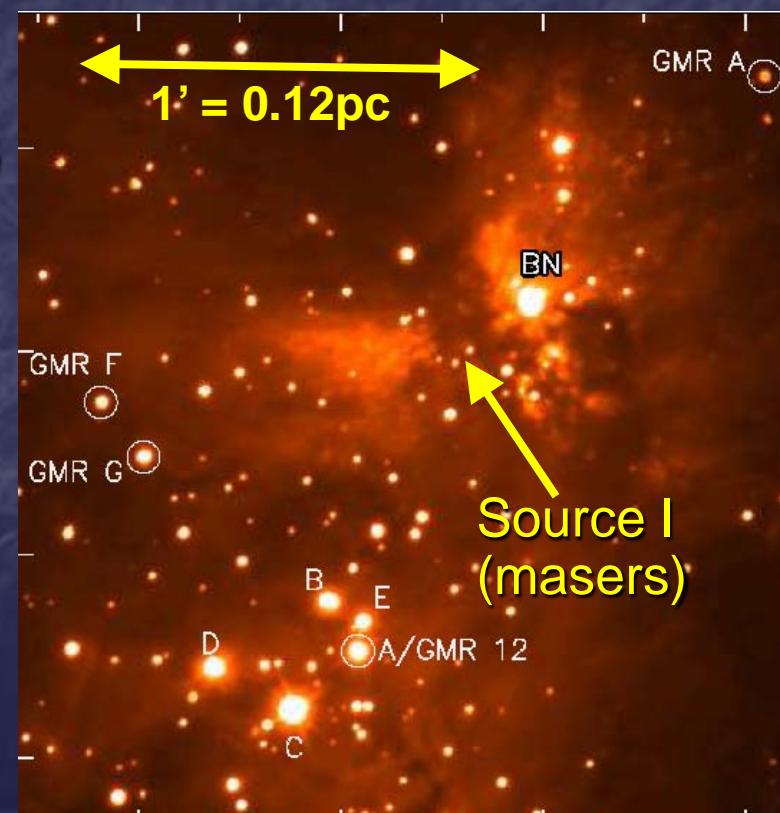

Orion Nebula

- VERA: H₂O and SiO masers in Orion KL
 - 437+/-19 pc (H₂O maser: Hirota et al. 2007)
 - 418+/-6 pc (SiO maser: Kim et al. 2008)

- VLBA: continuum from WTTSSs

- 389 +24/-21 pc
(GMR-A: Sandstrom et al. 2007)
 - 414+/-7 pc
(4 WTTSSs: Menten et al. 2007)

(NIR image of ONC; Menten et al. 2007)

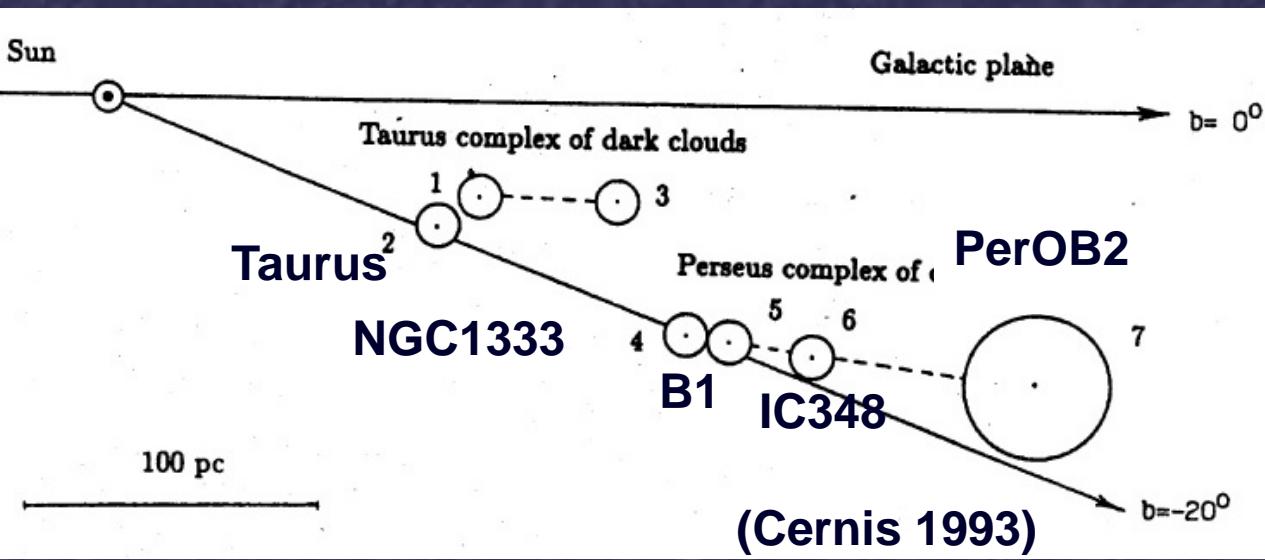

Perseus molecular cloud

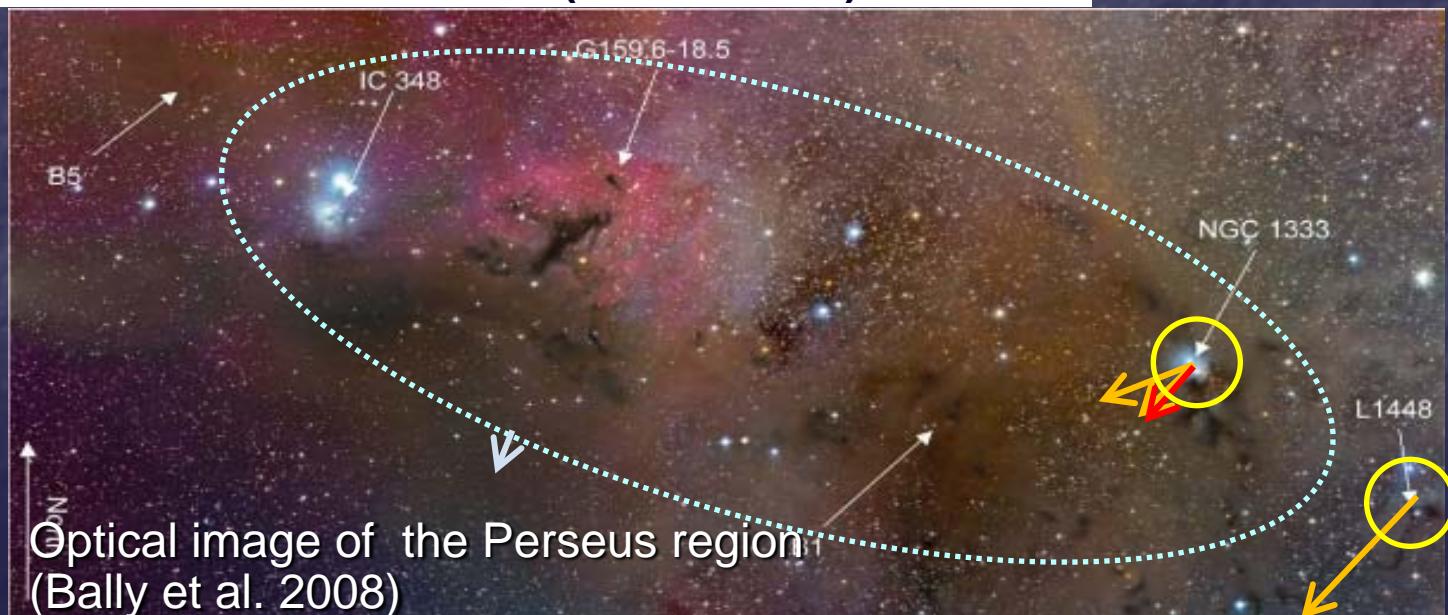

- NGC1333 (Hirota et al. 2008): $235+/-18$ pc
- L1448C (Hirota et al. 2010): $232+/-18$ pc
 - Photometric distance: 220 pc (Cernis 1990)
 - HIPPARCOS: 318 pc for Per OB2 (de Zeeuw et al. 1999)
- Proper motions similar to VLA/HIPPARCOS results

Perseus molecular cloud

Suggested by previous photometric observations
(Cernis 1993)

Other researches

- Ophuchus
 - VERA: 178^{+18}_{-37} pc (Imai et al. 2007)
 - VLBA: ~120 pc (Loinard et al. 2008)
- Cepheus
 - VERA: 764 ± 27 pc for L1204G (Hirota et al. 2008)
 - VLBA: 700 ± 40 pc for Cepheus A (Moscadelli et al. 2009)
- Consistent with each other
 - Small difference might be the depth of the cloud?
- Taurus, Serpens
 - VLBA (Loinard et al., Torres et al., Dzib et al.)

Current and future work

- Current --- Astrometry of H₂O masers
 - Orion-Monoceros, Perseus, Taurus: on-going
 - Ophiuchus and other regions: waiting for maser flare
- Future work
 - Wider-band backend (1G→4Gbps); continuum observations
 - East-asia VLBI (EAVN); powerful tool to study nearby YSOs
 - Collaboration with EVN and LBA; methanol masers
- VERA (and other VLBI arrays) will reveal 3-D structure of molecular clouds and local structure of Galaxy
